EXECUTIVE SUMMARY

EDP Renewables North America is developing of the Arkwright Summit Wind Farm (Project) in Chautauqua County, New York. In 2015, EDP Renewables North America contracted Western Ecosystems Technology, Inc. to conduct acoustic bat and mist-net surveys at the Project. The main objectives of the summer bat surveys were to: 1) to determine the summer presence/probable absence of the northern long-eared bat (NLEB) in areas potentially affected by construction activity and operation of the facility; and 2) determine sites where follow-up mist-netting for NLEB should be conducted.

Following the 2015 Indiana Bat summer survey guidance, the level of effort for acoustic surveys is to be determined as one survey station within each approximate 1-km segment containing suitable forest habitat blocks along linear survey area. US Fish and Wildlife Service defines suitable habitat for NLEB as any forest (e.g., deciduous, coniferous, mixed) or forested landscape feature (e.g., woody wetlands, forested riparian areas, shelterbelts. Desktop land-use/land-cover habitat assessment determined that the Project linear survey area in New York required 35 survey locations (27 of which were located within the Project and eight along the proposed transmission line route). If NLEB were positively detected at any of the acoustic survey sites then follow up mist-net surveys were conducted in the approximate location of the acoustic site. Presence/probable absence follow up mist-net surveys were conducted at one of the 35 acoustic sites.

Based on habitat assessment and US Fish and Wildlife Service recommendations, bat surveys were conducted at 36 sites. Acoustic presence/probable absence surveys were conducted at 35 sites with sampling occurring during 103 detector nights. NLEB echolocation calls were identified at one of the 35 acoustic sites. Follow up mist-net surveys were conducted at the one positive acoustic site in order to capture NLEB, and potentially conduct telemetry surveys, and locate roost trees used by this species if possible. Bat survey methods and the survey locations were provided to the US Fish and Wildlife Service. Qualitative review confirmed NLEB at one site (2.9%). NLEB are considered to be likely absent from 34 of 35 sites (97.1%).

Mist-net surveys were completed at the site on August 11 and August 12, 2015. A total of three bats (two eastern reds and one big brown bat) were capture. No NLEB were captured during 2015 mist-net surveys.

BACKGROUND AND PROJECT OVERVIEW

EDP Renewables North America (EDPR) is developing the Arkwright Summit Wind Farm (Project) in Chautauqua County, New York. In 2015, EDPR contracted Western Ecosystems Technology, Inc. to conduct acoustic and mist-net surveys for northern long-eared bats (NLEB; *Myotis septentrionalis*) at the Project. The main objectives of the summer bat surveys were to: 1) to determine the summer presence/probable absence of NLEB in areas potentially affected by construction activity and operation of the facility; and 2) determine sites where follow-up mist-netting for NLEB should be conducted.

Following the 2015 Indiana Bat summer survey guidance, the level of effort for acoustic surveys is determined as one survey station within each approximate 1-km segment containing suitable forest habitat blocks along linear survey area. USFWS (2015) defines suitable habitat for NLEB as any forest (e.g., deciduous, coniferous, mixed) or forested landscape feature (e.g., woody wetlands, forested riparian areas, shelterbelts). Desktop land-use/land-cover ("LU/LC") habitat assessment determined that the Project linear survey area in New York required 35 survey locations (27 of which were located within the Project and eight along the proposed transmission line route; Appendix A1). If NLEB were positively detected at any of the acoustic survey sites then follow up mist-net surveys were conducted in the approximate location of the acoustic site. Presence/probable absence follow up mist-net surveys were conducted at one of the 35 acoustic sites (Appendices A2 and A3).

Based on habitat assessment and US Fish and Wildlife Service (USFWS) recommendations, bat surveys were conducted at 35 sites. Prior to surveys being bat survey methods and the survey locations were provided to the USFWS. Acoustic presence/probable absence surveys were conducted at 35 sites (Appendix A2). NLEB echolocation calls were identified at one of the 35 acoustic sites. Follow up mist-net surveys were conducted at the one positive acoustic site in order to capture NLEB, and potentially conduct telemetry surveys, and locate roost trees used by this species if possible. The following report summarizes the results of acoustic and mist-net surveys conducted during summer 2015.

OVERVIEW OF BAT DIVERSITY

Eleven species of bats are found in New York. Those species include: the big brown bat (*Eptesicus fuscus*), eastern red bat (*Lasiurus borealis*), hoary bat (*L. cinereus*), northern yellow bat (*L. intermedius*), Seminole bat (*L. seminolus*), silver-haired bat (*Lasionycteris noctivagans*), Indiana bat (*Myotis sodalis*), little brown bat (*M. lucifugus*), NLEB, eastern small-footed bat (*M. leibii*), and tri-colored bat (*Perimyotis subflavus*). Of the 11 species known to occur in New York two are federally listed under the Endangered Species Act [ESA]. Indiana bats are listed as endangered and NLEB are listed as threatened under the ESA. In addition, the eastern small-footed bat is considered a New York species of concern. With the spread of white-nose syndrome (WNS) throughout the eastern US, several once common and abundant bat species, such as the little brown bat and NLEB, are experiencing population declines (Frick et al. 2010, USFWS 2013).

METHODS

Acoustic Surveys

Acoustic surveys were conducted following guidance in the 2015 Range-Wide Indiana Bat Summer Survey Guidelines, which is also used for NLEB presence/probable absence surveys (USFWS 2015) and the NLEB Interim Conference and Planning Guidance (USFWS 2014).

Acoustic surveys were conducted during a time period consistent with USFWS guidelines (June 22 through August 16; USFWS 2014, 2015). Bats were surveyed using AnaBat™ ultrasonic detectors (Titley Electronics Pty Ltd., NSW, Australia). Acoustic monitoring began before sunset and continued for the entire night. Survey duration at each site was a minimum of two nights. If weather conditions such as persistent rain (more than 30 minutes), strong winds (greater than 9 mph for more than 30 minutes), or persistent cold temperatures (below 10°C [50°F] for more than 30 minutes) occurred during the first five hours of a survey night, then that site was surveyed for an additional night (USFWS 2014, 2015). Weather conditions were checked with the following weather stations, which can be found on Weather Underground's Wundermap (<http://www.wunderground.com/wundermap/>): Dunkirk, NY. To maximize the quality of recorded echolocation calls, detectors were positioned at least one meter off the ground, at a 45° angle or greater, and with PVC tube weatherproofing (Britzke et al. 2010, USFWS 2014, 2015). Sensitivity was set to 6 on all detectors.

Bat calls were quantitatively identified using Bat Call Identification (BCID; version 2.7c; Allen 2013) and Kaleidoscope (version 3.1.2; Bats of North America classifier version 3.1.0; Wildlife Acoustics). While using BCID, the appropriate state (New York) was selected, and the default settings were adopted. For Kaleidoscope, the appropriate state (New York) from the Bats of North America classifier (version 3.1.0) was selected, and the most sensitive (i.e., most liberal) setting was used. For both software settings, Indiana bats were not included as a possible species in the models because they aren't known to occur within the Project. All calls identified as NLEB by automated ID software were verified via qualitative call analysis by a biologist experienced with acoustic identification and who met required USFWS qualifications (Jeff Gruver; USFWS 2015). As well, if a night exceeded the maximum likelihood threshold (p-value < 0.05) for NLEB, all files from that night received qualitative review. If call sequences were not characteristic of NLEB bats, contained distinct calls produced by species other than NLEB bats, or were of insufficient quality, they were reclassified as another species or as unknown. NLEB were considered present at sites with probable NLEB calls flagged by automated analysis **and** verified by qualitative review. NLEB were considered likely absent from sites with no probable NLEB bat calls or from sites with probable NLEB bat calls that were overruled by qualitative analysis.

Mist-Net Surveys

Follow up mist-net surveys were conducted following guidance in the 2015 Range-Wide Indiana Bat Summer Survey Guidelines (USFWS 2015) and the NLEB Interim Conference and Planning Guidance (USFWS 2014).

Mist-net surveys were conducted during a time period consistent with USFWS guidelines (May 15 through August 15; USFWS 2014, 2015). Standard two-ply, 50 denier, nylon mist-nets with a mesh size of 38 millimeters (1.30 inches) were used at all mist-net sites. Mist-netting began at sunset and continued for at least five hours. Nets were checked every 10 minutes. Net locations were typically established at least 30 meters (98.4 feet) apart within each mist-net site whenever possible. Disturbance in the form of noise and movement were minimized at all net locations. WEST surveyed two mist-net locations per site. Mist-nets were located in the general vicinity of acoustic detection sites in suitable bat habitat. Specific mist-net sites were determined on-site by permitted bat biologists with NLEB research experience. If weather conditions such as persistent rain (more than 30 minutes), strong winds (greater than 9 mph for more than 30 minutes), or cold temperature (below 10°C [50°F] for more than 30 minutes) occurred during the netting period, then those net nights were re-surveyed. All mist-net surveys were performed by staff permitted and approved by USFWS (Permit # TE234121-7), and New York Department of Environmental Conservation (NY-DEC; Endangered/Threatened Species: Scientific License #84) to capture and handle NLEB.

For each mist-net night the date, start and end time, site description, site coordinates, mist-net specifics, and weather data (temperature, cloud cover, wind speed, precipitation, and moon phase) were recorded. All captured bats were identified to species. In addition, sex, age, reproductive condition, body mass (grams), forearm length (millimeters), and capture status (recapture/new) were recorded. To assess exposure to White-Nose Syndrome (WNS), a Reichard Index score (0-3) was recorded for all captured bats. To prevent cross contamination of captured bats with *Pseudogymnoascus destructans*, the fungus that causes WNS, the USFWS WNS decontamination protocols were followed for all mist-netting efforts. Captured bats were measured and processed immediately and were usually released within 15 minutes. Species of bats captured were photo-documented. For NLEB and little brown bats, voucher photographs of species-specific identifiable features (e.g. head, body, calcar, foot, toe hairs etc.) were taken. Numbered metal forearm bands were attached to NLEB and little brown bats.

RESULTS

Acoustic Surveys

WEST conducted acoustic surveys from June 22 - August 16, 2015. UTM coordinates and brief site descriptions for each site are listed in Table 1. Maps and photographs of acoustic survey sites are included in Appendix A and B, respectively. Acoustic surveys were completed at 35 sites for a total of 103 detector nights. Some survey sites were surveyed for longer than the proposed 2 detector nights due to inclement weather, equipment malfunction, or scheduled

access to survey sites. At one survey site (AW-3), two detectors were placed in proximity to each other to ensure proper operation of the acoustic equipment. Number of bat calls per detector night varied between the two programs (51.8 for BCID; 75 for Kaleidoscope; Table 2). While Kaleidoscope identified more files as bat calls, BCID identified a slightly higher percentage of the calls. BCID recognized 5,340 bat call files and identified 5,270 files to species (99%), while Kaleidoscope recognized 7,723 bat call files and identified 7,333 files to species (95%) (Tables 2 and 3).

Automated acoustic ID software identified potential NLEB at one site. NLEB calls from were confirmed by qualitative analysis at one of 35 acoustic survey sites (2.9%). Based on these data, NLEB are considered to be present at one site and likely absent at 34 sites (97.1%). The site with confirmed NLEB acoustic positives is: AW-26. Follow-up mist-netting was conducted at AW-26.

Mist-Net Surveys

Mist-net surveys were completed at one site on August 11 and August 12, 2015 (Tables 4 and 5). Maps and pictures of mist-net sites are included in Appendix A and C, respectively. A total of three bats were captured at the site, including two eastern red bats and one big brown bat (Table 5). No NLEB were captured during the 2015 mist-net surveys. Photos of captured bat species are included in Appendix D, and capture details for all bats can be found in Appendix E.

CONCLUSION

To meet the objectives of the study, acoustic surveys were conducted to determine presence/probably absence of NLEB and to determine the locations of follow-up mist-netting surveys. Based on the acoustic results it was determined that there was summer presence of NLEB at site AW-26. Follow-up mist-netting surveys at the site resulted in no captures of NLEB.
